## **1. Introduction**

The main purpose of this interim report is the transference of analytical data to Thiokol Corporation and the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) to allow for in-process review and focusing of the remaining geotechnical and analytical effort on those areas found to be of continued concern.

At the outset of this project, nine sites within Longhorn Army Ammunition Plant were designated as potential areas of concern. These areas have been investigated geotechnically and analytically through the logging of existing soil conditions, as well as the sampling of groundwaters, surface waters, sediments, and soils at each of the study areas. The technical results associated with the geotechnical investigation have been submitted under separate cover in November 1982 as Interim Technical Report No. 1. This document contains the analytical data and field sampling methodology used for this survey.

The following sections of this interim report will rely heavily on other documents previously prepared by Environmental Protection Systems, Inc. (EPS) and already submitted to Thiokol and USATHAMA.

## **2. Sampling and Analysis**

### **A. Sampling Methods**

Sampling methods used during this study are presented in detail in Appendix G of this document. The manual which constitutes appendix G was issued to all field personnel, and the field sampling protocol established in this manual was strictly adhered to. Of notable exception to the methods prescribed in our field sampling protocol manual would be the method used by EPS to collect soil samples. Due to site-specific field conditions encountered during the survey, soil samples were routinely collected from each study area with a very narrow, long-nosed shovel. Specifically, a hole 1 foot deep was dug, and then a slice

approximately 5 inches wide and 1 inch thick was removed from the side of the hole using the shovel.

All other sampling procedures outlined in Appendix G were strictly adhered to. EPS collected all water and sediment samples during a one-week period from November 16-21, 1982. Ninety-seven percent of all samples collected at LHAAP were collected in a three-day period from November 17-20, 1982.

#### B. Parameters and Analytical Methods

A list of all parameters for which EPS was certified for the Longhorn AAP Contamination Survey is presented as Table 1A in Appendix G.

Prior to the initiation of all sampling, EPS underwent a rigorous certification process which was administered by USATHAMA. Before the first samples were collected at LHAAP, EPS achieved certification for the parameters listed in table 1A in Appendix G and all matrices to be tested. Table I provides a list of all paramaters for which EPS was specifically certified for this survey, and the associated assigned method numbers and detection limits.

A detailed description of each of the analytical procedures used during this survey can be found in EPS's quality assurance document previously submitted to Thiokol and USATHAMA.

#### 3. Quality Control

A detailed description of the quality control plan established for the Longhorn Army Ammunition Plant Contamination Survey is presented in EPS's quality assurance document. All data generated during this survey, unless otherwise noted, met the rigid analytical requirements presented in EPS's quality assurance document. A data summary sheet for each batch of samples (water, soil, and sediment) and analytes which did not meet quality control requirements, including the rationale used by the

FQAC to override the system, is presented in Appendix E. All results generated during the analytical portion of the survey for explosives, anions, GC/MS, and GC/EC parameters met the quality control requirements established in EPS's quality control program.

However, considerable problems were encountered in the analysis of metals in natural samples of water and soil collected at LHAAP. All water samples collected during the survey were analyzed in four groups of 17 batches each, or 68 discrete batches (AAX through ADM). The quality control for each batch included a duplicate and two spikes at different levels. The duplicates analyzed for all four batches of water samples had at least 2 of the 17 parameters being tested out of specifications with respect to precision. Most, if not all, of these problems were caused by the high concentration of a particular element encountered in natural samples, along with the resulting impact of numerous dilutions on the analytical scheme. The quality control for the spikes indicated several conditions under which our analytical process would be considered out of control; however, upon closer examination, it was determined that these problems occurred with the parameters for which EPS was certified semiquantitatively. The body of data which was used in the preparation of the quality control charts was rather limited for these parameters, and after review by the field quality control coordinator, it was determined that a re-calculation of the existing tables was in order. Accordingly, results for all spikes for batches presented in this report for atomic absorption water samples fell within reasonable and expected quality control ranges.

All soil and sediment samples collected at LHAAP were analyzed by EPS in three groups of 17 batches each, or 51 discrete batches (AEU through AGS). Here, too, results for several parameters in certain batches were found to be outside of the pre-established quality control limits set for this project. On closer analysis it was found that these quality control anomalies were all associated with high background levels in the blanks and spiked matrices, and the associated need for several dilutions, as well as, for many of the semiquantitative analytical parameters, an

unrealistic accuracy target range based on limited analytical data generated during the quality assurance certification.

#### 4. Analytical Results

##### A. Data Reports

All analytical results generated during this survey are presented in Appendices A, B, C, D, and F. Appendix A contains all analytical results generated for groundwater sampling sites. Appendix B contains analytical results for samples collected at all surface water sites. Appendix C contains all analytical results for sediment sampling sites. Appendix D contains analytical results for samples collected at soil sampling sites. Appendix F contains results for all compounds isolated during the screening analyses (HPLC, GC/EC, and GC/MS) which have either been identified, or are being reported as unidentified compounds at this time. All results are presented by analytical category according to each station sample.

##### B. Detection Limits

The detection limits established for this project are presented in Table I. These detection limits were generated during the certification process which EPS underwent for both the Longhorn and Lone Star Army Ammunition Plants, and generally represent a composite detection limit for all analyses conducted by EPS for USATHAMA.

#### 5. Preliminary Conclusions

Of the nine areas studied in-depth during this survey, only two have been demonstrated as having the potential for being a source of contamination which might conceivably migrate off-post.

The first area of continued concern is the TNT area. Wells 114 through 119 do not indicate the existence of any groundwater contamination in

this area. The geotechnical results to date indicate that this area has soils of relatively low permeability, and, therefore, it is not surprising that, although soil contamination does exist at this site, the explosive contaminants present have not penetrated into the groundwater. Our analyses indicated relatively widespread and locally heavy contamination of sites within the TNT area for several of the explosive compounds tested.

Our sampling effort for this project took place during a period of very heavy rainfall. The rainfall (exact meteorological data will be presented in the final report) caused flash flooding in the small creeks and bayous which run through LHAAP just prior to the sampling of the surrounding surface waters associated with the TNT area. Even though the area was subjected to a tremendous flushing from the heavy rainfall, traces of 2,4,6-TNT (0.78 ug/l) were still found in surface water at Station SW006, as well as a relatively high level (206.90 ug/l) of 2,4,6-TNT. Also detected at this station were 2,4-DNT (23.40 ug/l) and 2,6-DNT (13.65 ug/l). Inasmuch as these concentrations of explosive compounds were detected at this site immediately downstream from the TNT area, and additionally considering that traces of 2,4,6-TNT (2.27 ug/l) and nitrobenzene (6.27 ug/l) were found at Station SW002, which is further downstream from the TNT area, this potential source of contamination warrants additional investigation.

During this survey one other site, which had been preliminarily identified as an area of concern, has been tentatively confirmed as a potential contamination source based on the analytical data presented. This area is the current and active burning grounds and associated rocket motor casing washout pond. Many of the wells surrounding the pond have high concentrations of several halogenated organic compounds.

Other sites within the initial nine general areas of concern have been determined to have localized low levels of contamination; however, data gathered to date would not support the imminent potential for migration off LHAAP.

## 6. Recommendations

A detailed review of the analytical and geotechnical data thus far produced for this survey is now in progress. However, some preliminary recommendations are evident from an initial review of the existing data. These recommendations pertain to those areas found to be of significant continuing concern with respect to their potential for having hazardous substances which might migrate off LHAAP.

1. It is recommended that, since major groundwater contamination was found in one area (active burning grounds), the majority of the additional geotechnical investigation be centered on the wells at the active burning grounds, with specific emphasis on those wells surrounding the rocket motor washout pond.
2. It is recommended that additional wells be installed in the wooded area between the rocket motor washout pond and the Harrison Bayou floodplain. This recommendation is based on the fact that many of the wells surrounding the pond were highly contaminated with halogenated organic compounds and that this contamination was not uniformly distributed from the apparent source of the contamination. The data indicates that there are major differences in the amount of contamination in wells that were equally distant from the apparent contamination source (rocket motor washout pond). Because of the fact that this area's soils have relatively higher permeability than other sites within LHAAP, and because the initial geotechnical report indicates that this area is probably underlain by discontinuous layers of material, it is very possible that the contamination from the rocket motor washout pond follows a very specific and localized pathway into the groundwater. The wells presently installed around the pond are too close to the pond for us to establish with any precision the extent of groundwater contamination in this area. Since it is predicted that the general groundwater flow from this site is towards Harrison Bayou, we recommend that at least six to eight wells be established at

distances of approximately 300 feet and 500 feet from the northeastern and northwestern edges of the rocket motor washout pond.

3. It is recommended that additional water and sediment samples be collected along the entire length of the main drainage course leaving the TNT area at Stations SW001, SW002, and SW006. Additionally, another sampling station should be established in the drainage course leaving the TNT area just prior to its confluence with the north bayou inlet to Caddo Lake. It is suggested that additional samples be collected during a period of normal rainfall at all sediment sampling points. It is further suggested that water samples be collected at surface water Station SW006 every 30 minutes during a storm water hydrograph. Samples collected during the rising and falling hydrograph periods should be analyzed for the presence of explosive compounds. This additional data will be vital in determining whether or not the concentrations previously observed in the surface waters at these sites were an anomaly caused by the very heavy rains in the area, or simply a fraction of the concentrations normally found in the system prior to major flushing.
4. It is further recommended that tissue samples from bottom-feeding fishes in the area of the north bayou inlet to Caddo Lake be analyzed for the presence of explosive compounds and their degradation products.
5. It is suggested that several additional borings be made in area 080 (the suspected TNT burial site) for analysis of explosive compounds. Since traces of explosives were found in bottom soil from one bore hole in this area, and considering that the sampling at this site was totally random, it is suggested that additional historical information be gathered, if possible, and that more specific, and possibly deeper, bore holes be dug for analysis of sediment samples.

## INTRODUCTION

The importance of a well-planned, well executed and documented sampling program cannot be overstated. It is the foundation on which the analyses and, ultimately, all decisions are based. Because of this fact, EPS has developed the following document to provide in one book all of the information which should be needed by the field sampling crew to comply with the LHAAP contamination survey Scope of Work and, additionally, to insure a specific predetermined protocol is regorously implemented. This document contains the sampling plan which will be used. Deviation from this plan cannot be accepted except under the most unusual of circumstances and then only with the approval of the FQAC and the proper documentation.

### **General Sampling Sites and Required Sample and Analytical Categories**

The monitoring station locations, parameter coverage, and sampling frequency have been specified by USATHAMA in a manner suitable to meet all objectives of this study. The design has taken into consideration past and existing ambient monitoring programs which may have been conducted, as well as the existing environmental conditions and past history associated with the utilization of the different sampling site locations.

Table 1A provides a list of analytical categories being investigated during this study. Tables 2A-4A provide a brief sampling point description and listing of stations to be sampled and analytical categories to be tested associated with well water, surface water/sediments and soils respectively. Figures 1A-6A provide the general location of well water, surface water/sediment and soil sampling points as well as site specific locations for selected monitoring well sites.

FIGURE 4A

LONGHORN ARMY AMMUNITION PLANT  
EXISTING AEHA WELLS NEAR EVAPORATION  
POND IN THE BURNING GROUNDS

## The Preparation and Selection of Specific Sampling Sites

No. 1: Monitoring well sampling site preparation. Upon arrival at the monitoring well sampling site, the upper well casing shall be cleaned using approved water and wiped dry before unplugging. A clean piece of polyethylene plastic sheet shall be placed on the ground to protect against possible contaminants caused by sampling equipment touching the ground. The height of the water column shall be determined and a calculation done to determine the standing volume of water in the well casing. Five times this calculated volume of standing water shall be removed prior to the extraction of any well water samples for analysis. Table 5A contains a list of standing water heights with associated water volumes for 2" monitoring wells. The purged water shall be bailed out into a calibrated pail in order to determine volume removed. The pail shall be attached via a hook to the existing well protection pipes and the bailing pipe shall be coiled into the pail as the bailer is removed from the well. Before dumping the contents of the pail, the conductivity of the water which has been purged out will be determined. If the well recharge rate is very slow, i.e., six hours or more required to achieve 90% recovery an alternate purging method may be used. This method will involve the bailing of the well twice to remove all standing water, allowing a minimum of 16 hours between the bailing cycles and after the final cycle before the sample is collected. Once the appropriate volume has been bailed from the test well, the well water sample can be collected as outlined in the subsequent section.

No. 2: Surface Water Sampling Site Selection. The surface water sampling sites have been generally located on Figure 2B. The exact location of the surface water sampling sites shall be determined at the time of sampling. The determination shall be jointly agreed to by representatives of EPS and the LHAAP representative. The site should be chosen for their ease of sampling and for their representativeness of the water course under investigation. Attempts should be made to select the site which has relatively calm or slow moving water. Sampling sites

should be located, if at all possible, upstream from manmade water course obstructions such as bridges and roadway culverts. Prior to the sampling at any of these points, the contractor will be responsible for providing a means of marking the sampling point to insure that a reoccupation of the sampling site can be accomplished within a reasonable period of time (3/4 iron pipe with Station # inscribed). The contractor will also make a permanent record of these sampling points on an installation map which will be provided by the LHAAP representative.

No. 3. Sediment Sampling Point: The sediment sampling points will be at the same location as the surface water sampling points. The specific selection criteria outlined above takes into consideration the requirements for identification of a specific sampling point for sediment analyses.

No. 4: Soil Sampling Point Selection and Preparation. The general areas of soil sampling have been indicated on Figure 3A. Within each of these areas the exact sampling points remain to be selected. This process will take place by a joint inspection with a representative of EPS, USATHAMA and a representative of LSAAP. The contractor will mark each of the specific five sampling points within each sampling area, which will be sampled for surface soils. The contractor will be responsible for developing a sketch of each area and the location of the representative sampling sites. Prior to the collection of any sample at any one of the points within the eight identified areas, the sampling crew will carefully remove all surface vegetation, rocks, leaves, and other organic debris. An area of approximately four feet square should be prepared in this way in order to insure no contamination from surface organic material.

#### The Collection of Samples

No. 1: Well Water. After the well has been prepared as outlined above, well water samples can be drawn for the variety of analyses to be conducted. The field sampling crew should consult the LHAAP, groundwater sampling log sheet (Matrix 1) to determine the exact type and number of specific samples which are

required at the particular well being sampled. The log book will indicate the sampling site identification number for each bottle as well as the specific categories being tested and whether or not duplicate samples will be required for this particular station. Each log sheet will contain data on the ground water status and volumes which need to be removed from each well. Prior to filling the bottles both the bottles and their caps will be thoroughly rinsed with the well water being sampled. The field technicians will take every precaution to insure that the sample bottles and well samples are not contaminated by surrounding soil or wind-blown material. After the bottles have been rinsed they are to be filled quickly and capped. In order to insure that no cross contamination takes place during sampling of ground water for the Longhorn Army Ammunition Plant Contamination Survey, EPS Laboratories will install a discrete PVC Bailer in each of the 53 monitoring wells. This bailer will pre-cleaned at EPS's Laboratory and will be used only in this pre-designated well site. For those monitoring wells which require modified or protracted bailing operations, the sampling equipment will be temporarily left hanging inside the wells throughout the sampling period.

No. 2: Surface Water Sampling. Surface water samples will be collected directly in the bottles provided for use by EPS. The field sampling technician will wade into the creek or stream at the pre-designated location and will hold the sample bottle upstream from his location at a depth equal to approximately one half of the total depth of the sampling point. Alternately samples may be taken in the sample bottles with a hand held apparatus which can be used from a boat off a bridge. The technician will remove the cap from the bottle and allow the bottle to be filled at the appropriate depth. The first sample taken in each bottle will be discarded and used to rinse the field sampling container. The field sampling technician will repeat this process to collect his field sample. The field sample will be immediately capped after collection. The field sampler will take every precaution to insure that bottom sediments are not disturbed to the point where they are collected

in the water sample. It should be noted that bottom sampling may be taking at the same time as the collection of water samples (immediately after water samples).

No. 3: Sediment Sampling. Sediment samples will be taken at each of the 20 sites listed in Table 3A. The sampling at each station will consist of the collection of at least five (5) two inch cores of surface sediment, which will be taken across the stream profile. These cores will be taken with a one foot long, two inch inside diameter stainless steel coring device with lexan core liners. The cores will be placed in a one gallon glass container. Enough material will be collected to fill a one gallon glass container with sedimentary deposits. The field technician should collect extra cores at various locations across the stream profile in order to insure that one full gallon of sedimentary material is collected at each site. As in the case with water samples, all of the coring devices shall be thoroughly washed with deionized water after the collection of samples from each individual station and the pre-cleaned lexan liner changed to avoid any cross contamination of future sampling sites.

No. 4: Soil Samples. Soil samples will be taken from each of the eight areas indicated in Figure 3A and described on Table 4A. Within each of these eight areas, several discreet one gallon samples will be collected. Each of these discreet samples will be made up of several cores taken in a four foot square area. The samples will be collected with a one foot long, one and one half inch inside diameter stainless steel coring tube or a small hand held auger. Approximately eight to 12 cores will be collected to fill the one gallon bottle in each of the five sampling points associated with each of the eight areas designated in Figure 3A. A total of 31 specific sampling sites will be sampled. The field sampling technicians will be collecting one duplicate sample in every one of the six general sampling areas (as designated in the soil sampling log book Matrix 4). In those cases where duplicate samples are being taken, they should be done simultaneously and every other core removed from the sampling site should be placed in an alternate one gallon sample container. All sampling equipment should be thoroughly rinsed with deionized water between each specific sampling site to avoid any possible cross contamination. At

several locations, five foot deep cores will be taken and these cores split in an upper and lower half to determine the potential location of specific contaminants. This will be accomplished by driving a two inch core one foot into the ground and removing the material for analysis and then by augering down one foot and taking an additional one foot core from this location and so on down to the five foot level. This methodology will eliminate the potential for cross contamination of a single five foot core driven from the surface down to the five foot level.

#### Treatment in the Field

A great deal of the sample treatment will be accomplished once the samples are received at the analytical laboratory. However, we will review each analytical category being sampled for and any special treatment which is necessary for water samples being taken for each of these samples. Soil Samples will not require any special sampling treatment. Samples being taken for analytical category one and five, which will be analyzed by high performance liquid chromatography (HPLC), will not have any field preservative added to them. These samples will be collected in a one gallon amber bottle. They should be filled to the top of the bottle and sealed as tightly as possible. These samples should be stored from the point of collection at 4 °C until they are delivered to the laboratory.

Samples being collected for analytical category number two from wells and surface water sites will also not be preserved in the field in any way. These samples will be collected in one quart amber bottles which have been stored with deionized water in them. The deionized water will be poured out, the sample collected and filled to the top of the bottle, and the cap immediately placed on the bottle. These samples will also be stored at 4 °C until their arrival at the main laboratory.

Samples collected for analytical category number three from well waters will not be preserved in any way. They will be stored at 4 °C after collection and after arrival at the main

laboratory they will be filtered and then preserved with nitric acid to a pH of less than two.

Samples collected for analytical category number three from surface waters will be preserved in the field, using nitric acid. One half of a millimeter of Ultrix Nitric Acid will be added to each of these samples before they are capped and stored at 4 °C.

Samples collected for analytical category number four will require the collection of a one gallon water sample as well as a small 40 ml water sample (collected in duplicate). Neither of these two samples will be preserved; however, care should be taken to insure that the 40 ml sample collected in the specially provided vial is filled to the very top and that no air space exist prior to the placement of the vial cap back on the sample. Both the 40 ml sample and the one gallon sample destined for analysis in category four will be stored at 4 °C.

Samples collected for analytical category number six will require the collection of samples in one gallon amber bottles. Once again these samples will not be preserved in the field; however, they should be stored at 4 °C prior to reaching the main analytical laboratory.

#### **Labeling and Logging-in of Field Samples**

The positive identification of field samples requires that a systematic approach be taken to the labeling and recording of collection data at each specific sampling site. Therefore, a log book system has been developed and incorporated into this document for use during this survey.

There are four specific log books provided, one for each matrix type. These log books are located on the pages listed below.

<u>Matrix/Sampling Site</u>	<u>Log Book Pages</u>
1/Groundwater	30-135
2/Surface Water	136-142
3/Sediments	143-146
4/Soils	147-152

In association with the sampling log books provided, a complete set of stick-on labels and tie-on tags have been prepared for each sample bottle to be collected. These labels are contained within individual packets which have been identified for each station. The field sampling technician should consult the appropriate log book to check on the number and kind of samples to be collected at each site. Once he has collected all of the samples, the bottles should be thoroughly wiped dry, then the packet of labels associated with each sampling site should be removed from its box and each label affixed to the appropriate bottle. Additionally, each tag should be tied or wired to the appropriate bottle as well. The field sampling technician should not leave a particular sampling site until all of the labels provided are attached to the appropriate bottle which now contains the sample. In those cases where duplicate sets of samples are being taken as designated on the field sampling sheets, two packets of labels are provided for the duplicate bottles which will need to be collected. The labels provided in the individual packets have already had the sampling station number, the matrix number, and the analytical category number affixed to them. It will be the responsible of the field sampling technician to put the sampling time and sampling date, as well as checking the appropriate field preparation notes and signing each tag with his initials. Once all of the samples have been collected, labeled, and tagged, the field technician will be responsible for checking the appropriate boxes on the field log book and writing down the date and time of the field sampling and any other pertinent notes in the boxes provided. Once all of the samples have been collected and checked in the manner outlined above, the field sampling technician will initial in the box provided in each line, or on each sheet of the log book. The initialling in this box indicates that all of the samples have been collected and checked and are now ready for storage for ultimate transportation to the laboratory. All of the different size and type bottles used in the collection of field water samples should be placed back into their original shipping containers. Once each container has been filled with bottles, a sample manifest will be prepared as discussed in a subsequent section.

Soil and sediment samples will be labeled and logged in in their respective log books. A complete set of tags has been provided for all soil and sediment samples just as was done with the water samples. In the case of soils and sediment samples, however, only one sample (two samples in case of duplicate stations) will be collected at each site. Although this will be simpler than the water sampling, because of the fact that only one sample will exist from each site, the importance associated with that sample will be much greater for there will be no chance for utilization of alternate samples should a sample be found to be nonexistent. Therefore, upon collection of a particular soil sample, the bottle should be wiped clean and the stick-on label should be affixed immediately. The appropriate information which should be provided by the field technician should be added on to the already partially completed label. Additionally, the tag provided should be wired onto the neck of the bottle in a secure fashion and the same information should be added onto the tag. The appropriate boxes should be checked and filled in on the sediment and soil log book, and once the sample has been labeled and secured, the field sampling technician should sign the particular line of the log book indicating that a complete sample had been taken and identified for future use.

#### The Preparation of the CDIR Form 13-2.1, 1 September, 1978

The chief of the field sampling crew will be responsible for making an entry on the CDIR Form 13-2.1, 1 September, 1978, for each sample bottle taken during this survey. A copy of this form is included as Figure 7A. In the upper left hand corner of this form there are seven slots under the title of Gang Punch. Slots 1 and 2 should be filled in with the initials LS. Slot 3 and 4 should have the initials SA. Slot 5 should have the initials C. Slot 6 and 7 will vary depending on the type of sample being collected. For our use the following initials will be placed in slots 6 and 7 as is needed:

1. GW -- Groundwater
2. SW -- Surface Water
3. SE -- Sediments
4. SO -- Soils

INS = INSTALLATION  
FA = FUNCTIONAL AREA  
T = DATA TYPE  
FIL = DATA FILE

SC = SAMPLING TECHN. CODE  
MTH = METHOD  
MEA = MEASUREMENT  
B00 = DATA FILE

PRE = PRECISION  
INSTR = INSTRUMENT  
EXPN = EXPONENT  
ACCUR = ACCURACY

Columns number eight through 12 need to be filled in with the Julian date for sample collection. For the purposes of this project, the Julian date will be construed as meaning the numerical day of the year preceded by the year date. Therefore, January 1, 1982, will be 82001 and November 16, 1982, will be 82320. Columns 13-15 should be filled in with the initials PRI (Preliminary Survey Phase I). Column 16-19 should be filled in with the site type which will be a four letter abbreviation for the particular types of areas to be sampled and will provide you with the following list which may be used during the study:

1. Creek -- (CREK)
2. Ditch or Drainage -- (DTCH)
3. Lake -- (LAKE)
4. Pond -- (POND)
5. River -- (RVER)
6. Spring -- (SPRG)
7. Stream -- (STRM)
8. Standing Water -- (STWA)
9. Sump -- (SUMP)
10. Soil Surface -- (SURF)
11. Well -- (WELL)

Columns 20-29 should be filled in with the site identification which should be left justified and should be listed as LHAAP and the Station number. Sampling depth should be listed in centimeters in columns 30-33. The sample technique should be listed in column 34 and the following is a list of letters which will be used for the types of sample which will be conducted:

B = Bailer  
G = Single graph sampler  
T = Tube core sampling

Columns number 35-39 should be left blank by the field sampling crew as well as columns 40 and 41. Columns number 42-47 should be filled in with the sample number code on each label. The code will consist of the sample number up to three digits, a one digit matrix code, and a one digit category code. The rest of the CDIR form can be left blank until a later date.

## The Preparation of a Sample Manifest

After samples have been collected and logged in and the CDIR Form 13-2.1 has been completed, the samples should be placed in their shipping cases for transport to EPS Laboratory. This process should take place at the sample collection site if at all possible, and as different types of samples are placed back into their respective cases, certain specific information about each of them needs to be recorded on the sample manifest form . A copy of this sample manifest has been included as Figure 8A of this document. The chief field sampling technician will log each sample bottle in; he will write in the site number, matrix code and analytical code (these three pieces of information make up the sample identification). He will also put the date and time of the log-in down and he will then put the number of the shipping case in its appropriate spot and also include any notes about the sample condition or any other pertinent information. Once all of this information has been logged in;, the chief sampling technician will initial the second to the last column on the manifest indicating that the sample has been secured in an appropriate case and has been logged in for shipment. The sample manifest has been designed to hold information on 20 discreet samples and, in many cases, this will mean that one manifest will hold information about bottles contained in up to five different shipping cases. The manifest will be maintained by the chief of the field sampling crew and will be transmitted along with the samples at the time of shipping to the laboratory facility.

### Maintenance of Chain of Custody of Samples

The chief of the field sampling crew will be responsible for the maintenance of a clear chain of custody of each of the samples taken during the LHAAP Contamination Survey. The field sampling crew chief will see that once samples are logged in on the manifest and in the sample collection book that they are secured in a location which only he has direct access to (an example of this would be a locked refrigeration unit, room or a locked and refrigerated vehicle). The samples should be maintained either in direct site of the field sampling chief or under a locked condition until such time as they are transferred to an employee of EPS to transport the samples to the designated EPS laboratory. On the back of each sample manifest sheet is a certification statement which will allow for the documentable transfer of samples from the custody of the chief of the field sampling crew to the individual assigned with the responsibility of transporting the samples to the analytical laboratory. The appropriate information needs to be completed on each manifest at the time of transference of the samples for transport. An example of the certification statement for transference of samples is included as Figure 9A.

### Transportation of Samples to the Laboratory

Water samples will be transported to EPS under refrigeration either using large insulated ice chest or a refrigerated truck. Samples which are destined for analysis in the laboratory should be transported as soon as possible to limit the holding time for those analytes particularly prone to degradation after collection. All water and soil samples collected should be maintained at approximately 4 °C until they are received at EPS's Jackson and Pensacola facilities.

The Transference of Sample Custody

The sample custody transference document has been incorporated into the certification statement on the back of each manifest sheet. See Figure 9A. At the time samples are delivered to EPS's Jackson and Pensacola facility, they will be checked in by the FQAC and he will initial each line indicating that each sample has been received. Additionally, he will sign the certification document in the appropriate spot certifying the receipt, time and date.
